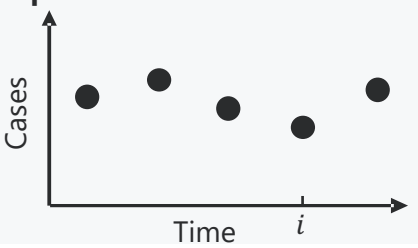
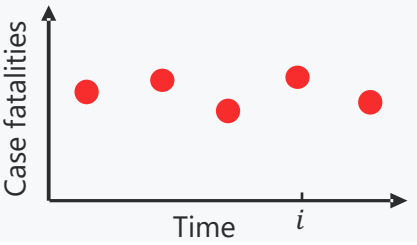
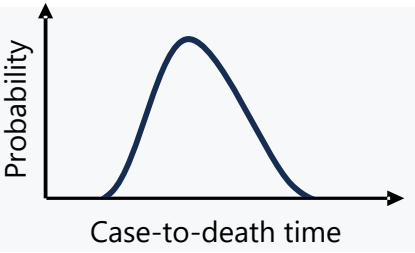
Input data





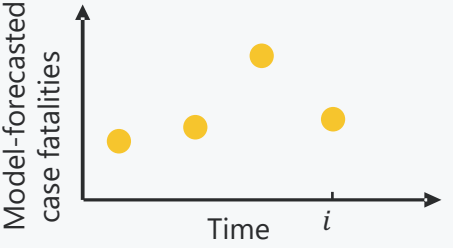
Distribution

Assume a case-to-death time distribution (e.g., Lognormal)



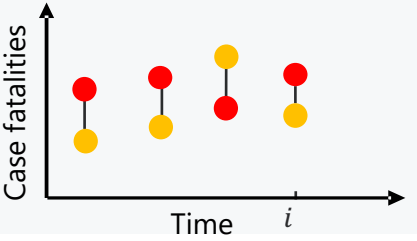
Model

Create a model-based forecast of case fatalities up until time-point i using eq. 2. The forecast depends on cases data, the parameters of the assumed distribution of case-to-death times, and an assumed case fatality ratio



Fitting

Search for parameters that minimize the errors between the model-forecasted case fatalities and actual case fatalities (e.g., minimizing the mean squared error using particle swarm optimization)



Optimized parameter values

Case fatality ratio and case-to-death time distribution parameters
